1 Introductory Material

1.1 ACKNOWLEDGEMENT

The project team would like to thank Michael Olson and Radoslaw Kornicki from Danfoss for their support on this project. We would also like to thank Dr. Wang for advising our team.

1.2 PROBLEM STATEMENT

As the agriculture and construction industries require autonomous solutions for increased safety and productivity the need to sense objects in the equipment path increases. There are many solutions on the market today using cameras and LIDAR. These solutions have limitations in weather and low light conditions. We were tasked with creating a system using radar to eliminate these limitations. RADAR is able to operate in the dark. It is also immune to the effects of low light, rain, snow, and fog.

Our project consists of two main components: the implementation of a radar system and the development of a deep learning model. The radar system will allow us to detect objects in many different conditions. The deep learning model will identify objects in the equipment’s path. This will allow for a notification to the equipment operator of objects in the vehicle’s path and in the future, fully autonomous operation.

1.3 OPERATING ENVIRONMENT

The operating environment for the system will be on agriculture and construction equipment. This will require the system to be able to withstand water and dust from the operating environment and the vibrations associated with operation.

1.4 INTENDED USERS AND INTENDED USES

The intended use is for certain agricultural vehicles and construction equipment that are a key area for our client. The long term use case is fully autonomous operation of machinery. It can also be used as an operator aid for safety.

1.5 ASSUMPTIONS AND LIMITATIONS

Assumptions:

- The operating conditions for the equipment will be normal and not abusive.
- The system will be mounted in an area that is protected from impact.
- The system-on-a-chip and radar will be able to operate in a rugged environment.

Limitations:

- The system will only operate up to 15 mph. This will cover a large range of agriculture and construction equipment.
- The system will not be 100% immune to sensor blockage by dust and dirt.
1.6 Expected End Product and Other Deliverables

For this project, our deliverables are a whole system including a radar module working with a deep learning model running on a system-on-a-chip to perform object localization and classification. The system will notify the vehicle operator via an LCD screen in the cab of the objects’ positions and types. The delivery date is December 2018. This system will be used for a demo on a piece of construction or agriculture equipment for our client.

Other deliverables include proposals regarding our radar and system-on-a-chip selection, reports on which deep learning platforms are most suited for use in mobile applications and a final report regarding the feasibility of implementing radar in construction and agricultural applications. The delivery date of all reports is December 2018. The delivery date of proposals to purchase the system-on-a-chip and radar will be February 2018 and March 2018, respectively.
2 Proposed Approach and Statement of Work

2.1 Objective of the Task

Our objective is to evaluate various radar technologies for Danfoss and through a combination of digital signal processing and deep learning, perform object detection and localization. By December 2018, we will have selected a radar option, a computing system adequate for a rough environment, designed and trained a neural network with data collected from the radar system, and implemented it on a vehicle to alert an operator of the presence and location of unique objects.

In order to provide value to Danfoss, we will also include a report evaluating various radar technologies, deep learning platforms, and computing systems to assist them in making a business decision when deciding to implement this technology in the future.

2.2 Functional Requirements

The functional requirements for the proposed design focus on robust detection and robust operation in agricultural and construction environments. A list of functional requirements is shown below.

1. The system shall have a range of 60 meters.
   a. Rationale: A range of 60 meters is required for early detection and identification. A machine traveling at 15 mph will cover 60 meters in less than 10 seconds. This range is allows for an object to be detected with sufficient time for action.

2. The system shall function on machines travelling at up to a speed of 15 mph or 6.7 m/s.
   a. Rationale: Most agriculture and construction equipment travels at speeds in the range of 5 mph to 15 mph. A max speed of 15 mph will allow for the majority of applications to be covered.

3. The system shall have angular range of ±30°.
   a. Rationale: An angular range of ±30° is required to detect objects in the vehicle’s path with sufficient time to stop.

4. The system shall have a processing speed of 15 frames per second.
   a. Rationale: The system needs to detect an object with sufficient time to react. A frame rate of 15 frames per second on a vehicle traveling approximately 15 mph or 6.7 m/s means the vehicle will travel no further than 0.5 m between each frame update.
5. The system shall detect objects greater than 0.4 m size.
   a. Rationale: A width of 0.4 m is the width of human shoulders. Detection of a human is, at minimum, required for safe operation of the system.

6. The system shall be weather resistant to water, dust, and shock.
   a. Rationale: Danfoss’ target applications involve heavy machinery that works in tough environments.

7. The system shall have a probability of missed detection less than 0.3.
   a. Rationale: A probability of 0.3 means that for each subsequent frame, the probability of missing an object multiple times approaches zero, which will yield a sufficiently short stopping distance.

8. The system shall have a probability of false alarm less than 0.3.
   a. Rationale: A false alarm, though undesirable, will be a safer alternative than a missed detection.

9. The system shall run off of a 12V power supply.
   a. Rationale: This voltage is easily available from a selection of batteries with also a range of amp hours. It is also easily available on a heavy equipment chassis. A step-up converter or inverter is acceptable.

10. The system shall fit inside 1’x1’x1’ space.
    a. Rationale: Space is limited on a vehicle, so our design must be compact enough to not obstruct operator view or regular vehicle operation.

11. The system shall detect at least 4 classes of objects.
    a. Rationale: Our system should detect people, cars, construction equipment, and buildings.

12. The system shall/should operate in the temperature range from -40 to 125 degrees Fahrenheit.
    a. Rationale: This is a common operating range for automotive sensors.

### 2.3 Constraints Considerations

As part of the project, we must evaluate various radar options, deep learning platforms, object detection networks, and computing systems. Evaluation of these systems will be centered on the functional requirements, but the behavior of the full system cannot be
known without implementing all combinations of each option. Therefore, a written report regarding behavior of individual components is necessary to justify our choices.

Because this project will ultimately lead to a business decision from Danfoss, cost of the system must be considered. We will strive to minimize cost, but not at the expense of our functional requirements.

Our code must be well commented and accessible to the client. The team will use Gitlab for version management of our software. This includes our neural network, data acquisition tools, and any low-level radar code.

Training data acquired during our project must be accessible to our client, yet secure. We will collaborate with Danfoss to ensure data collected (which may include imagery from their facilities) is secure to their internal standards.

For our code, group members will follow an agreed upon coding convention. Because we expect much of our code to be Python, we will follow PEP 8 - Style Guide for Python Code: https://www.python.org/dev/peps/pep-0008/.

The IEEE code of ethics will help guide our project, and ensure that our work does not violate the health and safety of our members, equipment operators, or Danfoss employees. We will ensure that any research performed is well documented and cited where necessary. This code of ethics is applicable to our project because we are working on something that may eventually be used to prevent injury, so ethical violations could indirectly cause harm eventually.

2.4 Previous Work and Literature

Literature surrounding the use of deep learning with radar focuses on either close-range object classification, or improvement of synthetic aperture radar.

A study from the University of St. Andrews showcases how short range radar can be used to differentiate between various objects, as shown here: https://sachi.cs.st-andrews.ac.uk/research/interaction/radarcat-exploits-googles-soli-radar-sensor-for-object-and-material-recognition/. This study is encouraging in that it shows how radar waves may be reflected in a unique way from different objects, but it does not show long-range applications, which is a significant shortcoming.

A research paper from Radar Conference [1] shows how deep learning can be used to improve the digital signal processing aspect of radar for synthetic aperture radar. This is beyond the scope of our project, as our project centers more around performing deep learning on radar imagery, rather than creating the imagery itself. Also, our system must perform real-time detection, not reconstruct an image later.

Literature more relevant to our project is related to object detection on RGB imagery. Several methods have been published that detail balances between speed and accuracy of
neural networks for object detection. This website provides a summary of various object detection methods that we may utilize for our project: https://towardsdatascience.com/deep-learning-for-object-detection-a-comprehensive-review-73930816d8d9. Of interest are Single-Shot Detector (SSD) (arXiv:1512.02325 [cs.CV]) and Faster RCNN (FRCNN) (arXiv:1506.01497 [cs.CV]). These network topologies take different approaches to detect objects. FRCNN proposes regions where an object might be, and evaluates each region to determine where an object lies in an image. SSD analyzes an image with fixed bounding boxes around what the CNN determines are relevant features to determine where an object is. For our purposes, SSD may be a better option to explore due to its improved speed compared to FRCNN, but at the expense of accuracy. Both network topologies deal with image resolutions beyond what our radar is likely capable of producing, so we may need to explore techniques for interpolation.

As a team, we must develop a network that can perform object detection in real time with sufficient speed and accuracy that does not rely on these existing networks. Because the data we collect is processed to produce an image, we have the advantage of the option to incorporate raw signal data into our network, which is not an option for state of the art object detection networks for imagery.

2.5 Proposed Design

In the end, our designed system must be able to detect and identify an object up to 60 meters away, as long as the object is within the 60 degree angle of view. The radar will be a Delphi ESR 2.5, connected to an NVIDIA Jetson TX2 through CAN.

A block diagram of our proposed design is shown in figure 1.

*Figure 1: System Block Diagram*
For the system output, the operator will be notified on an LCD display within the cab, connected to the Jetson TX2 via CAN. We will also explore other ways to notify other vehicle systems using the CAN bus, or the operator by the use of warning lights.

The system must be able to identify the object. To do so, our deep learning model built with Keras will perform classification.

The system must be able to operate in all normal weather conditions such as cold, hot, windy, rainy, etc. The Delphi ESR 2.5, as automotive radar, is well suited for the task.

2.6 TECHNOLOGY CONSIDERATIONS

Many different radar systems and deep learning APIs are available. It has been decided that Keras is going to most likely be the deep learning API for our system due to its simplicity, versatility, and a team member’s previous experience with it.

At the moment, the radar system by Walabot is being used as a test subject. This radar system does not have the range needed to meet design requirements, but it does come with an interface that is simple to operate. This system is being used as a testbench so that we can write scripts to convert radar data into distance and angle.

Texas Instruments offers a chip and another supplier has a radar system that meets our distance requirements but does not offer an interface. Also, the system is quite expensive and exceeds our client’s budget.

Again, due to the variety of radar systems in the market, a final decision has yet to be made on which radar system our team chooses.
2.7 SAFETY CONSIDERATIONS

If soldering circuitry becomes a task, burns are a possible risk. Typical solder temperatures range from 500-800 degrees Fahrenheit. The team member attempting to use a soldering station should have basic knowledge on how it operates.

Our design will eventually be tested on large machinery such as farm and construction equipment which will create safety risks. Personal protective equipment (PPE) and/or training may be required in order to avoid cuts, head trauma, slips, etc.

2.8 TASK APPROACH

Our task approach for the design can be visualized using the block diagram below. As of now, we have met with the client and determined system requirements. Next, the team will be reviewing those requirements and designing the system. Once the radar system, user interface, and radar chip has been selected, the design process of the overall system will be begin.

2.9 POSSIBLE RISKS AND RISK MANAGEMENT

The cost of our radar system, in total, will reach at least $6475, The Delphi ESR 2.5 costs $6175 while the NVIDIA Jetson TX2 cost $300. Due to the high cost of the system, it has taken longer than expected to receive these necessary items.
2.10 Project Proposed Milestones and Evaluation Criteria

Deciding on a particular radar system is our first key milestone. This radar will need to meet all functional requirements. When we believe we have found the correct radar we will purchase it. The next milestone will be hooking the system up. Once we have the system setup we will test to make sure all components work with each other by testing the input and output of the system. As long as information gets from input to the output we will know we have it set up correctly. The last key milestone will be a working deep learning model. Our final product will be tested on our client’s test track in Ames. If our product detects the object it is supposed to, then we know it works. The test plan for this is in section 2.13.

2.11 Project Tracking Procedures

Our group is using GitLab and Google Drive to track our process. Tasks will be assigned to individuals for tracking, and all relevant documents will be shared on Google Drive to ensure all group members have access.

2.12 Expected Results and Validation

Our desired outcome is to be able to detect four different classes of objects. Not only do we want to detect these objects, but we want the driver to be able to see where the object is and what the object is via a user interface. Again, we will confirm our system works at a high level by testing it at the Danfoss test track. The test plan in the next section describes in detail how we will confirm all requirements are met.

2.13 Test Plan

We will have many different levels of testing. Some testing will be just software testing of the deep learning model. Some will be bench testing of the radar system. We will have some full system testing in a lab environment. Lastly, we will take our system to Danfoss’ test track for a real world test. We will test the system with objects at 10, 20, 30, 40, and 50 meters. We will test the system with objects moving at various speeds, along with the machines speed.

In order to meet each functional requirement, a simple test will be performed for each of the following:

1. The system shall have a range of 60 meters.
   a. Test: All classes of objects to be detected will be placed at 60 meters away from the system and we will observe if they are detected.

2. The system shall function on machines travelling at up to a speed of 15 mph or 6.7 m/s.
a. Test: The vehicle will travel at this top speed, and we will observe if it adequately performs detections (to be specified how in requirements 7 and 8).

3. The system shall have angular range of ±30°.
   a. Test: This is a RADAR and camera specification and does not require a test.

4. The system shall have a processing speed of 15 frames per second.
   a. Test: The system will be allowed to run for several minutes, with each frame incrementing a counter. If the average speed is greater than 15 frames per second, it is sufficient.

5. The system shall detect objects greater than 0.4 m size.
   a. Test: An object 0.4 meters wide will be placed 60 meters away. The system must detect it.

6. The system shall be weather resistant to water, dust, and shock.
   a. Test: The system will be mounted on a vehicle, where it will be naturally exposed to dust, water, and shock. The radar we select will have an IP rating that is resistant to these dangers.

7. The system shall have a probability of missed detection less than 0.3.
   a. Test: The system will be tested multiple times. For each test case, we will observe if the system correctly detected the object. If the total number of frames without detections is greater than 0.3 times the total number of frames, our network must be retrained.

8. The system shall have a probability of false alarm less than 0.3.
   a. Test: We will run our network in a scenario with that should have no detections. For each detection, we will increment a counter. If this counter is greater than 0.3 times the total number of frames, our network must be retrained.

9. The system shall run off of a 12V power supply.
   a. Test: This is a requirement that will be determined by the radar and system on a chip selected.

10. The system shall fit inside 1’x1’x1’ space.
    a. Test: The radar and system on a chip must fit within this space. Enclosures designed by our team must also meet this specification.
11. The system shall detect at least 4 classes of objects.
   a. Test: Each class will be introduced to the system in a variety of scenarios.

12. The system shall/should operate in the temperature range from -40 to 125 degrees Fahrenheit.
   a. Test: All individual components purchased must at least have this operating range.
### 3 Project Timeline, Estimated Resources, and Challenges

#### 3.1 Project Timeline

<tbody>
<tr>
<td>1</td>
<td>01/08 - 01/21</td>
<td><strong>Schedule and Roles:</strong> We will be solidifying our schedule, roles, responsibilities, and allotting times for meetings. We will be discussing individual positions and we will be assigning tasks and deadlines for specific portions of the project.</td>
</tr>
<tr>
<td>2</td>
<td>01/22 - 02/04</td>
<td><strong>Target parameters, system requirements, and website:</strong> We will be working on improving our website. We will continue to update documents and responsibilities, which will be published. We will compile a &quot;system requirements&quot; to know what hardware we require to run processes. We will also be solidifying our choice for Radar during this time so we may begin testing.</td>
</tr>
<tr>
<td>3</td>
<td>02/05 - 02/18</td>
<td><strong>Final Selections:</strong> Our team will have decided on which radars are suitable, the deep learning platform, and what kind of system on a chip (SOC) we will be using as our onboard computer. Once selected, we can begin the testing process to narrow down a final combination of the three components.</td>
</tr>
<tr>
<td>4</td>
<td>02/19 - 03/04</td>
<td><strong>Testing:</strong> In this portion of our project, we will actually begin to run tests on our final radar/platform/SOC combination to see how it fares and to see if the real world results are what we expected. If our expectations are met or exceeded, we will proceed and begin to prep out deep learning model and run identification tests.</td>
</tr>
<tr>
<td>5</td>
<td>03/05 - 03/25</td>
<td><strong>Final Radar and SOC selected:</strong> This is the two week slot we have allotted in case we need to rethink our radar/platform/SOC combination. If we are satisfied with our primary combination then we will use these two weeks to begin training.</td>
</tr>
<tr>
<td>6</td>
<td>03/26 - 04/08</td>
<td><strong>Database of Radar Images:</strong> As we approach the end of our semester, the team will start collecting data and classifying it to run it through our deep learning platform so we can identify various radar signals as objects.</td>
</tr>
<tr>
<td>7</td>
<td>04/09 - 04/22</td>
<td><strong>Deep learning model:</strong> Once the database is complete we will run it through the deep learning model we selected. When it is ready, we can begin to load it onto our SOC to test it with real objects in front of it.</td>
</tr>
<tr>
<td>8</td>
<td>04/23 - 05/04</td>
<td><strong>Port data from radar to deep learning model:</strong> We will send the collection of data from the radar to the SOC to be run through the neural network. This way we can improve the accuracy of the net while building a bigger database.</td>
</tr>
</tbody>
</table>
3.2 Feasibility Assessment

We know of some major aspects where we know to be careful. We need to ensure that we remain within the scope of the project. We only want to focus on getting the deep learning model and the radar to work. If we begin to spend too much time on alternative forms of detection, we will be in over our heads. Therefore, we must implement and follow strict constraints.

Our radar and SOC also need to be feasible. To achieve this, we are choosing the most economically sound option for our project. We do not want to cut corners and choose cheap products, but at the same time we also do not want to be spending tens of thousands of dollars and hundreds of hours into the project. Along the way, we will consult our faculty advisor, client, and team members to ensure the products we choose are of the best quality with the most reasonable price tag.

3.3 Personnel Effort Requirements

This information is found on our [GitLab page](#). Each action item includes dates, assignees, and details all listed out the Issue Board section of our Git.

3.4 Other Resource Requirements

We will need to know how radars work. We will also need to understand how deep learning neural nets work, as well as how to use them with Python. For all of this information, we will be using YouTube, textbooks, and how-to books (ie. “For Dummies” series) as resources. We will also require some storage space, such as a server, for all the test data we use and collect.

In addition to this, when we are close to the end of our project, we will need heavy equipment and a test area to see how our technology fares in the real world.

3.5 Financial Requirements

We will need to purchase RADAR and a controller to go with it. We will also require funding for the server if we need it. Our major expenses are the radar unit itself and the controller.
4 Closure Materials

4.1 CONCLUSION

Our project is to develop a system for Danfoss to use on machinery such as tractors, loaders, excavators, and other heavy equipment that can use radar to detect objects. We will be utilizing deep learning to recognize objects in order for these vehicles to determine if there is a hazard in range of the radar.

We decided to use the Delphi RADAR because of its better range and wider field of view. This RADAR will be connected along with a camera to the Jetson TX2 computer which will then process the data and output our display to the LCD monitor in the cab of the machine. We hope to create a device that we can put into testing on Danfoss’ test track in Ames in order to show leadership and engineers from Danfoss the work we have accomplished and the system we have created.

With our collected data from this radar use deep learning to help decipher whether the objects in the view of the radar are a hazard or are not a hazard. This will then appear on the LCD with the classification of the object, and whether this object will be in the path of the vehicle or just a general potential problem.

With all of this accomplished we will have tested a new technology for Danfoss. This technology can help make safer working conditions and future autonomous operation possible. Hopefully, this technology will be feasible for future development into a product for our client, and a safer society surrounding the machinery our system is implemented on.
4.2 REFERENCES

4.3 APPENDICES
Delphi Electronically Scanning RADAR

Delphi has applied more than 20 years of radar experience to develop its award-winning electronically scanning radar (ESR). Leveraging expertise gained from radar production that began in 1999, Delphi brought ESR to market at a price that is helping make radar-based safety and convenience systems more affordable in the automotive market.

Delphi’s multimode ESR combines a wide field of view at mid-range with long-range coverage to provide two measurement modes simultaneously. While earlier forward looking radar systems used multiple beam radars with mechanical scanning or several fixed, overlapping beams to attain the field of view required for systems like adaptive cruise control, Delphi’s multimode ESR provides wide coverage at mid range and high-resolution long-range coverage using a single radar. Wide, mid-range coverage not only allows vehicles cutting in from adjacent lanes to be detected but also identifies vehicles and pedestrians across the width of the equipped vehicle. Long-range coverage provides accurate range and speed data with powerful object discrimination that can identify up to 64 targets in the vehicle’s path.

Delphi’s technologically advanced ESR uses proven solid state technology plus class-leading performance, packaging and durability to offer customers game-changing forward radar detection. The quality of data provided by Delphi’s system enables powerful functionality including adaptive cruise control, forward collision warning, brake support and headway alert.

- **ESR enables the following features:**
  - Adaptive Cruise Control with Stop & Go
    - Enhances driver convenience
  - Forward Collision Warning
    - Helps reduce the potential for an accident and injury
    - Helps reduce the potential for property damage
  - Brake Support
    - Helps reduce the potential for an accident and injury
    - Helps reduce the potential for property damage
  - Headway Alert
    - Provides distance information
    - Alerts driver when the preset time-gap to vehicle ahead is violated
Delphi Electronically Scanning RADAR

The Delphi Advantage

- Multi-mode, multi-application capability
  - Simultaneous long- and mid-range functionality allows one radar to be used for multiple safety systems including adaptive cruise control, headway alert, collision warning and mitigation and brake support
- Solid-state Technology
  - No moving parts
  - Extremely reliable
- Class-leading performance and durability
  - Resistant to vibration and extremely robust
  - Innovative design provides excellent multi-target discrimination plus precise range, approach speed and angle data
  - Dual-mode classification enhances object reliability
  - Simultaneous Transmit and Receive Pulse Doppler (STAR PD) Waveform provides independent measurements of range and range-rate and superior detection of clustered stationary objects
- Compact packaging
  - Complete radar module, including electronics, measures just 173.7 x 90.2 x 49.2 millimeters including mounting features
  - Compact design makes it easier to locate the sensor on the vehicle without compromising vehicle styling
- High value
  - Produced using processes proven in high-volume manufacture of engine control units
  - Proven manufacturing processes increase affordability for high-volume automotive segments where radar systems have not previously been available

### Description

**Jetson TX2 System-on-Module**

#### Security
- Secure memory with video protection region for protection of intermediate results
- Configurable secure DRAM regions for code and data protection
- Hardware acceleration for AES 128/192/256 encryption and decryption to be used for secure boot and multimedia Digital Rights Management (DRM)
- Hardware acceleration for AES CCM, SHA-1, SHA-256, SHA-384, and SHA-512 algorithms
- 2048-bit RSA HW for PKE boot
- HW Random number generator (RNG) /PRNG/0-50
- TrustZone technology support for DRAM, peripherals
- SEITSEC with side channel counter-measures for AES / RSA-3072 and ECC-512251 supported via PKA

#### Memory
- 128-bit DRAM interface | Secure External Memory Access Using TrustZone Technology | System MMU
- Memory Type: 4ch x 32-bit LPDDR4
- Maximum Memory Bus Frequency (up to): 1866MHz
- Memory Capacity: 8GB

#### Storage
- eMMC 5.1 Flash Storage
- Bus Width: 8-bit
- Maximum Bus Frequency: 200MHz (IS400)
- Storage Capacity: 32GB

#### Connectivity
- **WLAN**
  - Radio type: IEEE 802.11a/b/g/n/ac dual-band 2x2 MIMO
  - Maximum transfer rate: 600.7 Mbps

- **Bluetooth**
  - Version level: 4.1
  - Maximum transfer rate: 3MB/s

#### Networking
- 10/100/1000 BASE-T Ethernet | IEEE 802.3 based Media Access Controller (MAC) | Embedded memory

#### Peripheral Interfaces
- **XHCl host controller with integrated PHY:** (up to) 3 x USB 3.0, 3 x USB 2.0, 1 USB 3.0 device controller with integrated PHY
- 5-lane PCIe: two x1 and one x16 controllers
- SATA (1 port)
- SD/MMC controller (supporting eMMC 5.1, SD 4.0, SDHost 4.3 and SDIO 3.0)
- 5 x UART / 3 x SPI / 8 x I^2C / 2 x CAN / 4 x I2S: support IT8, RJM, LJM, PCM, TDM (multi-slot mode)
- GPIO

#### Operating Requirements
- Temperature Range: -25°C to 40°C
- Module Power: 7.5W (Max-Q) / 15W (Max-P)
- Power Input: 5.5V to 19.6V

#### Applications
- Intelligent Video Analytics, Drones, Robotics, Industrial automation, Gaming, and more.

---

* Refer to the software release feature list for current software support.

* GPU Maximum Operating Frequency: 1.3GHz supported in boost mode.
  - Product is based on a published Khronos Specification and is expected to pass the Khronos Conformance Process. Current conformance status can be found at www.khronos.org/conformance.

* CPU Maximum Operating Frequency: 1-4 core = up to 2.3GHz; greater than 4 core = up to 1.4GHz

* For max supported number of instances: bitrate not to exceed 15 Mbps per HD stream (i.e., 1080p30), overall effective bit rate is less than or equal to 240 Mbps

* Depends on board layout. Refer to Interface Design Guide for layout guidelines.

* Refer to the Interface Design Guide and Parker Series 8xC Technical Reference Manual to determine which peripheral interface options can be simultaneously exposed.

* Refer to the Jetson TX2 OEM Product Design Guide and Jetson TX2 Thermal Design Guide for evaluating product power and thermal solution requirements. See the software documentation for information on changing the default power mode (default: Max-P).
